A Difference in Aerobic and Anaerobic Energy Costs During Weightlifting

Sarah Shapiro, Deline Dwelly
Faculty mentor: CB Scott

Abstract
Energy expenditure is usually estimated by total oxygen uptake. However, with weightlifting, very little oxygen is utilized during the lift. The majority of oxygen uptake happens during recovery (Excess Post-Exercise Oxygen Consumption, EPOC). The purpose of this study is to determine the significance of the anaerobic and EPOC phases during weightlifting exercises in estimation of total energy cost. We gathered data from 42 subjects (60 averaged trials) aging between 18 and 35 years. Each subject chose a comfortable weight and lifted to a cadence of 1.5 sec up and 1.5 sec down. Tests were given on two different occasions. We used a metabolic cart to collect oxygen consumption (VO2), and EPOC measurements. Blood lactate measurements were taken to estimate anaerobic energy costs. Our data revealed that the contribution of anaerobic and EPOC phases, had the most significant impact on the total energy cost estimation.

Results/Discussion
The data shows that the contribution of the anaerobic component to the total energy cost during weightlifting exercises is significant. Although there is not a significant difference between the anaerobic and EPOC (recovery oxygen uptake) phases, it is clear, that they both greatly influence the final estimation of caloric expenditure.

As you can see, the standard deviations are quite high. This is due to the variability when comparing weightlifting exercises. Based on this research and collected data, we suggest that the anaerobic and post exercise components of weightlifting must be taken into consideration when estimating total energy expenditure.

Introduction
Recent studies have suggested that oxygen-only measurements are not providing an accurate estimation of total energy expenditure during weightlifting. There are data that suggest oxygen-only measurements underestimate the total energy cost of the work completed. Activities such as weightlifting, not only have an aerobic component, but also an anaerobic element that requires estimation. It is hypothesized that for the resistance exercise examined, the anaerobic component not only contributes significantly to the total energy expenditure, but will be greater than the aerobic expenditure component.

Data

* Exer O2 = 5.6 + 6.5 kJ
Anaerobic = 9.6 + 9.9 kJ
EPOC = 12.9 + 13.3 kJ

Key:
TEE = Total Energy Expenditure
Std Dev = Standard Deviation
KJ = KiloJoules
J = Joules
