Watershed Survey Sector Maps and Spreadsheets Appendix
Summary

The New Meadows River watershed covers 23 square miles in Cumberland and Sagadahoc counties, and is located in portions of the towns of Bath, Brunswick, Harpswell, Phippsburg, and West Bath. The New Meadows River drains south into Casco Bay. The New Meadows is a significant recreational and economical resource to the region.

In 2000, the New Meadows River Watershed Project conducted a survey of nonpoint sources of pollution in the upper portion of the watershed, located in Bath, Brunswick, and West Bath. In October 2002, the survey of the entire New Meadows River Watershed was completed. The lower watershed survey covered an approximately 12.15 square mile area in portions of Harpswell and Phippsburg. Volunteers from the watershed, Cumberland County Soil and Water Conservation District staff, the Maine Department of Environmental Protection, Maine Department of Marine Resources, and the Environmental Protection Agency documented sites where soil and sediment erosion was occurring.

Surveyors identified 72 sites that were impacting or have the potential to impact water quality of the New Meadows River. Twenty-five sites were located in Harpswell, while 47 were located in Phippsburg. When categorized by land use, identified sites were associated with residential areas (12), driveways (10), private roads (22), town and state roads (14), water access points (9), and commercial sites (5). Survey sites were evaluated according to impact on the New Meadows River, the technical level of planning and cost necessary to correct the problems.

The goal of the survey was to identify, prioritize, and raise awareness of existing sources of polluted runoff in the New Meadows River Watershed. Ideally, this information will be used to spur the watershed community to take future actions that will protect the quality of the New Meadows River for future generations to enjoy.
Introduction

The New Meadows River watershed is located in Cumberland and Sagadahoc counties, and covers the towns of Bath, Brunswick, Harpswell, Phippsburg, and West Bath. The 23 square mile watershed is covered by a variety of land uses including forested, developed, agricultural, and wetland. The New Meadows River drains south into Casco Bay.

Surprisingly, the New Meadows River is not a river at all. In fact, it has very little fresh water. Rather, the New Meadows River is a long, narrow embayment; an off-shoot of Casco Bay.

The New Meadows River is a significant recreational and economical resource to the region. A public boat launch and a marina are two examples of public access to the River, and locations such as the Basin in Phippsburg are considered havens for boaters. The River supports an extensive finfish, shellfish, and lobster fisheries. This high productivity is evident in the production from the New Meadows River flats over the past four years, which accounted for 7.5% of the total soft-shell clam production for Maine.

The New Meadows River is listed as a priority coastal water by the Maine Department of Environmental Protection (DEP). Additionally, Casco Bay Estuary, and therefore the New Meadows River, has been designated an estuary of national significance by the U.S. Environmental Protection Agency, as a nationally significant estuary threatened by pollution, development, or overuse.

Does the New Meadows River have a water quality problem?

One of the biggest pollution culprits in Maine’s water is polluted stormwater runoff from rain and snowmelt. Runoff occurs during and after storm events when soil with attached nutrients (such as phosphorus and nitrogen) and debris are washed into rivers and streams. Since it cannot be traced back to one particular source, this type of pollution is also called nonpoint source pollution or NPS.

In an undeveloped, forested watershed, storm water runoff is slowed and filtered by trees, shrubs, and other vegetation. The forest canopy decreases the impact of the rain, while the forest floor slows and filters runoff with its uneven ground and leafy debris. In a developed watershed, there is less tree canopy to protect the ground from raindrop impact. The uneven ground, its vegetation, and leaf litter have been altered or removed as well. In addition, storm water velocity and volume increase on impervious surfaces like rooftops, compacted soil, gravel camp roads and pavement, and does not always receive the filtering treatment the forest once
provided. Remember, fast water is hungry water. The faster water travels, the greater its potential to erode and carry away soil material and debris.

In the New Meadows River, the nutrient of concern is nitrogen. In marine waters, nitrogen acts like a fertilizer. Excess nitrogen leads to a rapid increase in algal production and possibly an algae bloom. As the algae dies it decomposes, which utilizes oxygen in the water. The resulting oxygen depletion may eventually lead to fish and shellfish death. Such an event ultimately results in habitat damage and an ecological imbalance. Microbial activity in the “deep hole” also appears to be releasing large quantities of nitrogen that may be indirectly affecting not only the “lakes,” but a portion of the upper river. In addition to a loss in aesthetic and recreational value, the stressed environment creates favorable condition for invasive plants.

Many of the issues that have occurred in the New Meadows River have been located in the upper portion of the river, and particularly in the “lake”, north of Route 1. Once fully tidal, this area has experienced periodic low levels of oxygen, and occasional algal blooms due to limited tidal flushing. These times of low oxygen may be tied to the sporadic fish kills, such as the pogie kill of the early 1990s. The “lake” also experiences clam flat closures due to rain, and the resulting runoff. Other flats are closed in portions of the river due to high bacterial counts or nearby faulty/failing septic systems.

While localized problems do exist, the New Meadows River remains a generally healthy waterbody. Still, development in the watershed, and along the coast of Maine in general, continues at a high rate. The population in the watershed has roughly doubled in the past 50 years! In order to maintain the health of this unique waterbody, it is vital that existing problems be located and addressed, and that potential problems be recognized and prevented from becoming an issue in the future. Remember, a healthy watershed yields good water quality.

What is being done to protect the New Meadows River?

Water quality data in the New Meadows River has been monitored since 1973. The Department of Marine Resources (DMR) regularly monitors stations along the river as part of its Shellfish Sanitation Program.

The Casco Bay Estuary Project (CBEP) has received a grant to establish a sustainable shellfisheries program. This project works to prioritize clam flats, remove or correct sources of bacterial contamination, and has developed a shellfish resource management plan. Additionally, the CBEP recently completed a five year project that examined the existence of toxic metals and chemicals in lobsters, mussels, and sediments.

Individual towns have remained actively involved in water quality sampling to assist DMR in ensuring compliance of open shellfish areas with national requirements. Towns have also worked to replace failing septic systems and overboard discharge systems, which are possible sources of bacterial contamination to the River and its clam flats.

Recognizing the fact that the New Meadows River does not conform to political boundaries, the New Meadows River Watershed Project was formed to address issues faced by the communities bordering the New Meadows River.
Two years ago, the New Meadows River Watershed Project, the DEP and DMR took the next step in protecting the river by conducting a watershed survey. That watershed survey was conducted in the upper portion of the watershed, in the Towns of Bath, Brunswick, and West Bath. Volunteers from the watershed documented sites where soil and sediment erosion occurred. Volunteer watershed surveys have been found to be one of the most effective ways to protect water quality by getting local residents involved in identifying existing and potential sources of polluted runoff.

This year’s survey focused on the lower watershed; an approximately 12.15 square mile area covering portions of Phippsburg and Harpswell. This survey completes the entire New Meadows River Watershed survey that began in 2000. This report contains a summary of the survey findings and recommendations for the lower watershed.

Local citizen participation was essential in completing the watershed survey. Ideally, this involvement will only increase. Through the leadership of the New Meadows River Project Steering Committee and assistance from groups and agencies concerned with the health of the New Meadows, the opportunities for watershed advocacy and education are numerous. Hopefully, this information will spur the watershed community to take further action that will protect the quality of the New Meadows River for future generations to enjoy.

**Purpose of the Watershed Survey**

The primary purpose of the watershed survey was to identify and prioritize existing sources of polluted runoff, particularly soil erosion sites, in the New Meadows River watershed. However, it was equally important to:

- Inform watershed residents that bare eroding soil is a primary source of water pollution. Nitrogen carried by this soil can cause over-fertilization of coastal embayments.
- Raise awareness about the connection between land use and water quality, and the impacts of polluted runoff.
- Make general recommendations to landowners for fixing erosion problems.
- Inspire people to become active stewards of land and water resources.
- Use the information gathered as one component of a long term river protection strategy.

Local citizen participation was essential in completing the watershed survey and will be even more important in upcoming years. Through the leadership of the New Meadows River Watershed Project Steering Committee and assistance from groups and agencies concerned with water quality, the opportunities for watershed stewardship and education are numerous.
Watershed Survey Methods

As with other watershed surveys in Maine, the New Meadows River survey used volunteers to identify erosion sites in the watersheds. Town leaders from Phippsburg and Harpswell and the Education Subcommittee of the NMR steering committee coordinated and publicized the project with help from the DEP and Cumberland County Soil & Water Conservation District (CCSWCD).

In October 2002, twelve volunteers attended a half-day training to learn about polluted runoff issues and how to identify and document problem areas. After the morning classroom session, volunteers divided into nine teams. Technical staff served as sector leaders, and provided guidance in the field.

Volunteers documented each erosion site by completing survey forms and site sketches, taking photographs and marking site numbers on tax maps. The majority of the survey was completed during the training, and teams surveyed the remaining areas over the following weeks.

Throughout the fall, a student from Bowdoin College and the CCSWCD organized the survey data, entered information into MS Excel spreadsheets and created the maps for the report, which was prepared by the CCSWCD.

Volunteers documented areas of active soil erosion. Signs of soil erosion include bare soil, rills or gullies (channels carved in the soil), exposed roots, road ruts and sediment deltas.

Volunteers and technical staff identified 72 sites that were impacting or have the potential to impact water quality of the New Meadows River. Sites were rated according to their relative impact to water quality, and their costs and technical level to fix based on the guidelines below. Identified sites were associated with residential areas, driveways, roads, water access, and commercial sites. Descriptions of these sites are on the following pages.
Key Findings from the Survey

- There is a manageable number of problems—most can be fixed with low to medium technical experience and cost.
- Most of the problems were found on residential properties, driveways, and private roads.
- In addition to the surveyed sites, numerous waterfront properties were observed to have little or no vegetated buffer at the water's edge. It is important to note that buffers of shrubs and trees do a much more effective job than bare ground or grass to keep polluted runoff from entering the New Meadows River!

**Potential Impact of Problems**
There were similar numbers of sites with low, medium and high impacts. Attention should be paid to all of the sites, since it’s the cumulative impact of all the sites that causes water quality to decline.

- Low—eroding site with limited transport off site, or small site with no evidence of rills or gullies
- Medium—sediment transported off site but does not reach high magnitude
- High—large area with significant erosion and direct flow to stream, ditch or river

**Technical Level Needed to Correct Problem**

- Low—property owner can accomplish the fix with or without proper reference materials
- Medium—technical person should visit the site & make recommendations
- High—site requires an engineered design

**Cost to Implement Recommendations**

- Low—less than $500
- Medium—$500 to $2,500
- High—more than $2,500
Residential Sites

Of the 12 sites associated with residential areas, 6 were low impact, 2 were medium impact, and 4 were high impact. Six of the sites can be fixed with little technical expertise and low cost.

**Common Problems Identified:**
- Slight or moderate surface erosion
- Bare and sparsely vegetated soil
- Lack of vegetated buffer along shoreline
- Direct flow of runoff to river
- Unstable construction site

**Recommended Solutions:**
- Seed and mulch bare soil
- Establish or enhance vegetated buffer
- Limit foot traffic in eroding areas
- Stop mowing the buffer
- Install silt fence around construction sites
- Install open-top culvert, waterbar, or other diverter

Residential sites make up a large portion of problem sites with sources of polluted runoff to the New Meadows River. These seemingly small problems can pose a significant threat to water quality. Fortunately, almost all of these sites can be corrected with easy, low cost fixes.

*It's the cumulative impact of all the sites that causes water quality to decline.*
Driveway Sites

The 10 driveway sites ranged from 50 to 400 feet in length. Three were low impact, and 7 were medium impact. There were no high impact sites. All of the sites could be fixed with low to medium cost and technical expertise.

Common Problems Identified:
- Slight to moderate erosion in ditch
- Unstable culvert inlet/outlet
- Poor shaping
- Moderate surface erosion
- Direct flow to a stream or the New Meadows River

Recommended Solutions:
- Reshape ditch and stabilize with grass or stone
- Reshape or crown driveway so that water flows to either side
- Install runoff diverters such as waterbars, open top culverts, broad-based dip, or rubber razors to get water off driveway
- Stabilize culvert, add plunge pool

Problems
- Moderate surface erosion
- Poor driveway shaping and ruts cause water to concentrate and erode the surface
- Direct flow of sediment to New Meadows River

Solutions
- Build up driveway with new surface material
- Reshape and crown driveway so water moves quickly from the surface to either side
- Install diverters such as waterbars, open top culverts or rubber razors to get water off driveway

Preserve water quality and save time, money, and wear and tear on your vehicle by having a well crowned driveway. Use adequate surface material and add diversions to direct runoff into vegetated buffers.

*It's great for watershed residents and it's great for the water!*
Private Roads

Of the 22 private road sites, 8 were high impact, 9 were medium impact and 5 were low impact. Proper construction and maintenance of private roads can help eliminate severe erosion problems and avoid the need for costly solutions.

Common Problems Identified:
- Slight to severe surface erosion
- Shoulder and ditch erosion
- Poor shaping
- Bare soil
- Unstable culvert inlet and outlet
- Direct flow to New Meadows River

Recommended Solutions:
- Install diverters such as waterbars, open top culverts or rubber razors to get water off road
- Crown road so that water flows to either side
- Install new culverts and armor inlets/outlets with stone
- Remove grader berms to allow proper drainage
- Install plunge pool or detention basin to trap sediment

Problems:
- Moderate road shoulder and surface erosion
- Clogged culvert
- Lack of ditch
- Direct stormwater flow to New Meadows River

Solutions:
- Clean out/maintain culvert
- Buildup and crown road surface
- Install ditches to collect road surface runoff
- Use turnout to redirect stormwater to wooded areas

Private Roads are the highest source (by number of sites) of NPS pollution to the New Meadows River.

While a one time fix may cost more up front, it will reduce overall maintenance costs on your road, ditches and vehicle.
**Town and State Roads**

Eleven town road problems and 3 state road problems were identified. Of these, 3 were high impact, 8 were medium impact and 3 were low impact.

**Common Problems Identified:**
- Direct flow of runoff to New Meadows River or tributaries
- Unstable culverts
- Eroding road shoulder
- Winter road sand build up
- Lack of/eroding/ improperly shaped ditch

**Recommended Solutions:**
- Install a catch basin/plunge pool at outlet of culvert to catch sediments
- Stabilize inlet/outlet of culvert with stone
- Establish vegetated buffer
- Proper shaping of ditches and backslopes
- Install turnouts to divert runoff to vegetated areas
- Remove grader berms, and crown/reshape road surface

**Problems:**
- Unstable and eroding culvert
- Eroding road shoulder
- Stormwater from road runs directly to tributary

**Solutions:**
- Vegetate road shoulder
- Stabilize and maintain culvert inlet/outlet
- Reroute stormwater from road shoulder to buffer on either side of culvert with ditching

Town and state roads sites identified in this watershed survey tended to discharge sediment directly to the New Meadows River or tributaries.

*Working with the Towns of Phippsburg and Harpswell and Maine Department of Transportation to fix and maintain priority road sites will save money and improve water quality.*
Water Access Sites

Nine water access sites (beach and boat access) were identified. Four sites were low impact, three were medium impact, and two were high impact sites.

Common Problems Identified:
- Moderate surface erosion
- Moderate to severe road shoulder and ditch erosion
- Bare soil
- Unstable access point
- Direct flow to a stream or the New Meadows River

Recommended Solutions:
- Build up road surface and crown
- Reshape ditch/shoulder and seed or riprap
- Install runoff diverters such as open-top culverts and waterbars
- Use infiltration pavers (tri-lock blocks) to stabilize access point
- Extend or establish vegetative buffer

Remember… It is the cumulative impact of all small, medium, and large sites that causes problems in the watershed!

Problems:
- Severe surface erosion on road
- Severe ditch erosion
- Direct flow of runoff and sediment to New Meadows River

Solutions:
- Use a more cohesive/less erodible surface material
- Install waterbars to divert runoff into wooded areas
- Regrade the road away from the water to encourage infiltration in established buffer.
Commercial Sites

Five commercial sites were identified in the watershed survey; three were medium impact sites, and two were low impact.

Common Problems Identified:
- Slight to moderate erosion in ditch
- Unstable culvert inlet/outlet
- Poor shaping
- Moderate surface erosion
- Direct flow to a stream or the New Meadows River

Recommended Solutions:
- Reshape ditch and stabilize with grass or stone
- Reshape or crown road so that water flows to either side
- Install runoff diverters such as waterbars, open top culverts, broad-based dip, or rubber razors to get water off road
- Stabilize culvert, add plunge pool

Problems:
- Moderate road surface erosion
- Runoff and sediment travel directly into cove
- Erosion occurring around culvert outlet

Solutions:
- Add new surface material and grade away from the cove
- Install runoff diverters, such as waterbars or open top culvert
- Stabilize culvert inlet/outlet
- Add vegetation with strong/extensive root system to hold soil in place

Protecting the quality of the New Meadows River makes good business sense!
Site Rankings

Sites in the spreadsheet were ranked according to three criteria:

- **Technical level to install** describes the degree of technical expertise needed to address a problem. A “low” tech level requires little or no specific technical assistance. For example, seeding and mulching an area that is relatively stable, but which requires vegetative cover to prevent additional soil loss from occurring. Sites with a “medium” tech level need to be visited by a technical expert who can make recommendations. A “high” tech level requires an engineered design.

- **Impact** was assigned by considering factors such as the size of disturbed area, slope, soil type, amount of soil that’s eroding, proximity to water or vegetated buffer, and size of vegetated buffer. “Low” impact eroding sites are those with limited transport off-site even if the site is large or a small site with no evidence of rills or gullies (channels cut into the soil). At “medium” impact sites, sediment is transported off-site, but the erosion does not reach a high magnitude. Large sites where there is significant erosion that flows directly into a stream, lake or ditch, were rated “high” impact.

- **Cost** is an important factor in planning for restoration. “Low” cost sites were estimated to cost less than $500 to fix. An estimate of $500 to $2,500 was rated “medium”. If the estimated cost to fix a site exceeded $2,500, a “high” rating was assigned.

**Important Points!**

Summaries of the NPS sites identified in the survey are listed in the Appendix. Sites are grouped in alphabetical order by land use or type. Each listing shows the map site number, the type of problem(s) encountered, location, and size or area, and recommended fix.

In addition to the surveyed sites, numerous waterfront properties were observed to have little or no vegetated buffer at the water’s edge. Not all of these sites were included in the survey results, but it is important to note that buffers of shrubs and trees do a much more effective job than bare ground or grass to keep NPS pollution from entering the New Meadows River.

This watershed survey was conducted from a land-based perspective. To fully round out an examination of the health of the watershed, this information should be used in conjunction with a water-based survey. A buffer tour or shoreline survey conducted from a boat would complement the information obtained from the watershed survey by gathering information about the health/existence of vegetated buffers, existence of gray water discharges, and/or septic system failures that would not be detected from the shore.

**VEGETATED BUFFER**

Areas of vegetation, left undisturbed or planted between a developed area and a waterbody that are used to capture pollutants being transported in surface water. Buffer vegetation can include trees, shrubs, and ground cover plants that are planted, transplanted, or growing naturally.
Where Do We Go From Here?

With the completion of the watershed survey, a big hurdle has been crossed in gaining control over the polluted runoff that is impacting the new Meadows River. This survey, in combination with survey for the upper portion of the watershed, can now be used for planning and implementation purposes.

Education should remain a priority in the watershed. Only when residents of the watershed understand and take ownership of their actions, both positively and negatively, will they take personal responsibility of protecting the health of the river.

Fixing the erosion sites identified in this survey will require efforts by individuals, MDOT, road associations, municipal officials in Phippsburg and Harpswell and the New Meadows River Watershed Project. To successfully protect the health of the entire New Meadows River, proactive steps need to be taken by all five communities in the watershed.

**Individual Citizens**

- Prevent runoff from washing sediment into the river. Detain runoff in depressions or divert flow to vegetated areas. Call the Cumberland County SWCD, Androscoggin Valley SWCD, or DEP for free technical assistance.
- Minimize the amount of cleared land and road surfaces on your property.
- Stop mowing and let lawn revert back to natural plants. Deep shrub and tree roots help hold the shoreline.
- Avoid exposing bare soil. Seed and mulch bare areas.
- Call your local Code Enforcement Officer before cutting vegetation within 250’ of the shore.
- Maintain septic systems properly. Pump septic tanks (every 2-3 years for year round residences and 4-5 years for seasonal residences) and upgrade marginal systems.
- Assist the DMR in conducting shoreline surveys to open clam flats and maintain those that are currently open.
- Visit [http://academic.bowdoin.edu/new_meadows/](http://academic.bowdoin.edu/new_meadows/) to learn more about what is going on in the watershed to protect the river, and how to get involved.

**New Meadows River Watershed Project Steering Committee/Interested Parties**

- Continue to utilize groups and contacts within and outside of the steering committee to bolster public support for watershed projects.
- Participate in the planning and implementation of a long-term watershed management plan for the watershed.
- Provide educational materials and guidance to residents of the watershed. Most of the identified erosion sites in this survey require minimal to moderate time, money, and expertise to fix. Holding a workshop has proven to be a positive way to share this knowledge. Workshops are an effective way to broaden citizens’ understanding of their impact to the river. Additionally, by involving local citizens, participants can take home the knowledge and confidence to implement erosion control methods at home.
- Develop long term educational outreach program, both in schools and the communities.
- Develop implementation projects to install conservation measures (BMPs) and apply for federal funds to complete the projects.

**Road Associations (or private roads without associations)**
- Minimize road runoff by doing regular, comprehensive maintenance. Form a road association if one does not already exist.
- Get a copy of “Camp Road Maintenance Manual – A Guide for Landowners.” It is a must for anyone managing a gravel road. (Call the DEP to order a free copy.)
- For more extensive problems, seek free technical help. Contact the Cumberland County SWCD, Androscoggin Valley SWCD or DEP to request technical assistance.

**Municipal Officials**
- Enforce shoreland zoning ordinance to assure full protection of the New Meadows River.
- Conduct regular maintenance on town roads in the watershed, and fix town road problems identified in this survey.
- Participate in and support long-term watershed management projects.
- Promote training for road crews, planning boards and conservation commissions.
- Work with DMR and DEP to remove sources of bacterial contamination along the shore.
- Request a workshop from the Nonpoint Education for Municipal Officials (NEMO) program.

---

*With a few exceptions, virtually all of the sites identified in the survey are significant to one degree or another. The cumulative effect of many “low” and “medium” impact sites can exceed that of any one “high” impact site. This should be considered when a strategy is developed to address problems in the watershed.*

*Remember, the long term health of the watershed depends on you!*
Permitting ABC’s

The protection of the New Meadows River is ensured through the good will of residents along the shore and through laws and ordinances created and enforced by the State and Town. In some cases, landowners will need to obtain permits prior to implementing some of the BMP’s suggested in this report.

How do you know when you need a permit?

- As a general rule of thumb, a permit is required from the Maine Department of Environmental Protection when soil is disturbed or vegetation is cut within 75 feet of a protected natural resource (i.e. lake, stream, or river) in an area where dirt or soil can wash into the water.

To ensure that permits for projects that will not result in significant disturbance are processed swiftly, the DEP has established a streamlined permit process called Permit by Rule. These one page forms (shown below) are simple to fill out and allow the DEP to quickly review the project.

The project partners encourage you to contact the DEP and Town Code Enforcement Officer if you have any plans to construct or relocate a structure, clear vegetation, create a new path or driveway, stabilize a shoreline or otherwise disturb the soil on your property. Even if projects are planned with the intent of enhancing the environment—such as installing some of the practices mentioned in this report—contact the DEP and Town to be sure.

How to apply for Permit by Rule with DEP:

1. Fill out a notification form. Forms are available from your town code enforcement officer or the Maine DEP office in Portland or Augusta.

2. Permit by Rule requires that you follow certain standards such as installing silt fence. It is important that you obtain a copy of the standards so you will be familiar with the law’s requirements.

3. The permit will be reviewed within 14 days. If you do not hear from DEP within 14 days, you can assume your permit is valid. If you bring the permit directly to a DEP office, you may be able to get your permit approved immediately.

~from Protecting Maine’s Natural Resources~Volume 1, DEP 1996
Glossary of Common Conservation Measures

**Crown**—High point that runs lengthwise along the center of a camp road or driveway. The high point slopes gently away from the center toward the outer edge of the road, allowing water to drain off the road and preventing erosion of the road surface.

Dripline Trench—Rock-filled trench beneath the roof edge drip line that collects and stores roof runoff until it soaks into the ground. Helps control erosion and reduce wear on the house by preventing backsplash. A typical trench is 6-8” deep and 12-18” wide and filled with 3/4” stone. Can also be used along the edges of driveways to encourage infiltration of runoff.

Open Top Culvert—Box-like structure that collects and diverts road surface runoff away from a sloped driveway or camp road. They are seldom recommended for year-round roads due to the likelihood of plow damage. Install at a 30º angle to the road and direct the outlet into a stable buffer. Clean out leaves and debris periodically.

Rubber Bar or Razor Blade—Structure that protrudes above the road surface high enough to intercept and collect water, while allowing traffic to pass over it. It is generally used on seasonal roads and driveways because of the likelihood of plow damage. Install at a 30º angle to the road and direct the outlet into a stable buffer. The rubber conveyor belt can be purchased at some hardware stores or Augusta Rubber (582-6200).

Turnout—A conservation practice used to direct runoff from a ditch (or road ruts) into a vegetated buffer. The turnout should have a flared end section that is level and lined with rock to spread out the flow.

Waterbar—Ridge (like a speed bump) that runs diagonally across a camp road, driveway, or path, typically at a 30º angle. Stops water from running down the road and diverts it to the side. Easy to construct and most appropriate for roads with low traffic volume. Needs to be rebuilt periodically.

Offers assistance with watershed planning and surveys, environmental education, engineering support, seminars and training sessions, and education on the use of conservation practices.

**Cumberland County Soil and Water Conservation District**
381 Main Street, Suite 3, Gorham, ME  04086
(207) 839-7839
Offers assistance with watershed planning and surveys, environmental education, engineering support, seminars and training sessions, and education on the use of conservation practices.

**Maine Department of Environmental Protection**
312 Canco Road
Portland, ME  04103
Toll Free (888) 769-1036 or (207) 822-6300
17 State House Station
Augusta, ME  04333
Toll Free (800) 452-1942 or (207) 287-7688
Provides permit applications and assistance, numerous reference materials, technical assistance, environmental education, project funding opportunities, and stewardship activities for lakes, streams, and rivers.

**Maine Department of Marine Resources**
PO Box 8
West Boothbay Harbor, ME  04575
(207) 633-9500
Provides information on the clam flat closures and general shellfish information; also impacts of septic systems and overboard discharges.

**Town of Phippsburg**
1042 Main Road
Phippsburg, ME  04562
(207) 389-2653

Phippsburg's Code Enforcement Officer provides information on Shoreland Zoning regulations.

**Town of Harpswell**
Mountain Road
PO Box 39
Harpswell, ME  04079
(207) 833-5771

Harpswell's Code Enforcement Officer provides information on Shoreland Zoning regulations.

**Publications**

# New Meadows River Lower Watershed Sites
